Bedrock Linux (1.0beta2 Nyla)

Table of Contents

Motivation

Real-world examples

Terminology

General usage

Planned for Nyla

Planned for future

Notice

- ▶ The content here describes the as yet unreleased Bedrock Linux 1.0beta2 Nyla.
- ▶ Everything is subject to change.

Motivation

Motivation — Debian/RHEL clones

- ▶ Debian and RHEL clones are stable.

Motivation — Arch Linux

- ▶ **Arch Linux** provides cutting-edge packages.

Motivation — Ubuntu

- ▶ **Ubuntu** is very popular.
 - ▶ Very commonly supported/targeted by third parties such as Valve.

Motivation — Gentoo

- ▶ **Gentoo** can automatically compile packages from source with various preferences set.

Motivation — OpenSUSE

- ▶ **OpenSUSE** has great out-of-the-box KDE support.

Motivation — Rebecca Black OS

- ▶ **Rebecca Black OS** has/had early support for Wayland.

Motivation — Bedrock Linux

Bedrock Linux can use software from other distros such that most of it “just works”.

- ✓ Debian/RHEL rock solid stable base?
- ✓ Arch's cutting edge packages? AUR?
- ✓ Gentoo's compilation automation options?
- ✓ Ubuntu's Unity? Mint's Cinnamon? OpenSuSE's KDE?
- ✓ Your-favorite-distro's your-favorite-feature?

All at the same time, transparently, cohesively.

Real-world examples

Real-world examples — Compiz/Xorg

- ▶ Debian's `compiz` works, but `xorg` is too old for new laptop
- ▶ Arch's `xorg` is good, but `compiz` is broken?
- ▶ So get `compiz` from Debian, `xorg` from Arch
- ▶ Yes, that just works under Bedrock Linux

Real-world examples — Easy Update

- ▶ New printer, old CUPS
- ▶ Get new CUPS
 - ▶ `# apt-get remove cups && pacman -S cups`

Real-world examples — Easy Fallback

- ▶ GNU `info` 5.2 broke piping
- ▶ Stick with 5.1
- ▶

```
# printf '#!/bin/sh\nbrc heisenbug info\n' >  
/bedrock/bin/info && chmod a+rx /bedrock/bin/info
```

Real-world examples — Rare packages

- ▶ The `sage` mathematics package is only in the repos for one distro - `Arch`
- ▶ So get it from `Arch`.

Terminology

Terminology — Stratum

- ▶ All of the files and processes are categorized into **strata**.
- ▶ **Strata** are *often* one-to-one with distro releases
 - ▶ Debian Wheezy **stratum**
 - ▶ Arch **stratum**
 - ▶ Fedora Heisenbug **stratum**
 - ▶ Slackware 14.1 **stratum**

Terminology — Stratum

- ▶ There are four **strata** attributes:
 - ▶ **local stratum**
 - ▶ The **stratum** providing a given file or processes.
 - ▶ **pid1 stratum**
 - ▶ The **stratum** providing the PID 1 process.
 - ▶ **global stratum**
 - ▶ The **stratum** providing the **global files**
 - ▶ **root stratum**
 - ▶ The **stratum** providing the **/bedrock files**
 - ▶ These are not mutually exclusive - one **stratum** could have all of these attributes.
-

Terminology — Local Files

- ▶ Files which could potentially conflict
 - ▶ `/etc/apt/sources.list`
 - ▶ `libc.so.6`
- ▶ **Bedrock Linux** avoids conflicts by having multiple instances of potentially conflicting **local files**.
- ▶ The instances are differentiated by **strata**
 - ▶ **wheezy** `/etc/apt/sources.list`
 - ▶ **trusty** `/etc/apt/sources.list`

Terminology — Explicit Local Access

- ▶ Explicitly specify desired **stratum**
- ▶ Execute:
 - ▶ `$ brc <stratum> <command>`
- ▶ Read/Write:
 - ▶ `/bedrock/strata/<stratum>/<file path>`
which **stratum**
 - ▶ `/bedrock/clients/wheezy//etc/apt/sources.list`
explicit access which file/filepath

Terminology — Direct Local Access

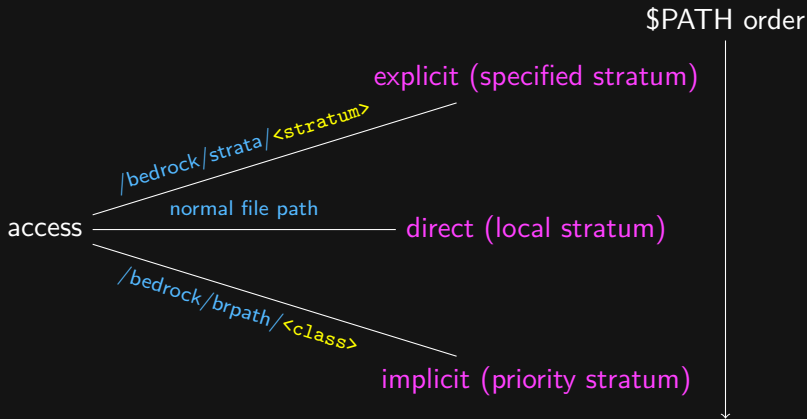

- ▶ Specify **local stratum**
- ▶ Normal file path

Terminology — Implicit Local Access

- ▶ Any **stratum** which can provide **local file**
- ▶ `/bedrock/brpath/<class>/<file name>`
- ▶ `/bedrock/brpath/bin/pacman`

The diagram illustrates the components of the path `/bedrock/brpath/bin/pacman`. A bracket under the first three parts (`/bedrock/brpath/bin`) is labeled "implicit access". A bracket above the word "bin" is labeled "class". A bracket below the word "pacman" is labeled "file name".
- ▶ Optionally specify priority in `/bedrock/etc/brp.conf`

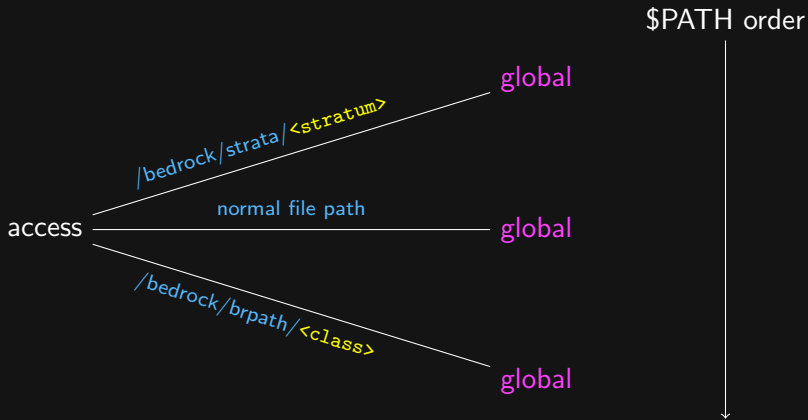

Terminology — Access local graph

Terminology — Global Files

- ▶ Files which need to be accessible everywhere for things to “just work”.
 - ▶ `/etc/passwd`
 - ▶ `/var/run/`
 - ▶ `/home/`

Terminology — Access global graph

Terminology — Singletons

- ▶ **Singletons** are things which you can only have one of at a time.
- ▶ Examples:
 - ▶ kernel
 - ▶ PID 1 (init)
 - ▶ bootloader
- ▶ Can use a **singleton** from any **stratum**, but only one at a time.
- ▶ Switch with a reboot.

Terminology — Singletons

- ▶ Don't like `systemd`?
 - ▶ `openrc` straight from **Gentoo**
 - ▶ `bsd-style init` straight from **Slackware**.
 - ▶ Or `runit`, `s6-init`, `cinit`, `uselessd`, `nosh`, etc
 - ▶ Like `systemd`?
 - ▶ Use a cutting-edge one from **Arch** or **Fedora**
 - ▶ If it breaks, reboot into a more proven release from **Debian** or **CentOS**
 - ▶ while keeping everything but the init the same - same home files, same DE, same everything.
-

General usage

General usage

- ▶ Day-to-day usage “feels” like every other distro.
- ▶ Run commands, edit files. Don’t have to do anything differently for **Bedrock Linux**.
- ▶ However, there are **Bedrock Linux**-specific things every so often.

General usage — Managing strata

To add a `stratum <foo>`

1. Get `stratum`'s files into: `/bedrock/strata/<foo>`
 - ▶ Install distro in a VM or bare metal, then copy or move or mount over.
 - ▶ Use something like `debootstrap/pacstrap/febootstrap/gentoo-stage3`.
 - ▶ Use `brg` utility (planned for future release).
2. Create `stratum`'s configuration file.
 - ▶ Create default: `# echo "framework = default" > /bedrock/etc/strata.d/foo.conf.disabled`
 - ▶ Don't have to use default, can configure as desired.
3. Enable `stratum`
 - ▶ `# brs up <foo>`

Can now use files commands from `stratum`.

General usage — Managing strata

Removing a `stratum <foo>`.

1. Disable `stratum`.

▶ `# brs down <foo>`

2. Remove `stratum`'s files.

▶ `# rm -r /bedrock/strata/<foo>`

General usage — Managing strata

What are the enabled strata?

- ▶ `$ bri -l`
 - ▶ `arch`
 - ▶ `heisenbug`
 - ▶ `jessie`
 - ▶ `sid`
 - ▶ `trusty`
 - ▶ `trusty32`
 - ▶ `wheezy`

General usage — Managing strata

Which **stratum**'s executable will run if I just run the executable?

- ▶ `$ bri -w vim` (or just `$ brw vim`)
 - ▶ **wheezy (direct)** → running **directly**, will run **Debian Wheezy**'s version (i.e. calling process is also from **Debian Wheezy**).

General usage — Managing strata

Which **stratum** is providing current process?

- ▶ `$ bri -n` (or just `$ brw`)
 - ▶ **wheezy** → calling process is from Wheezy **stratum**.
 - ▶ **Bedrock Linux** users often put this in their shell prompt.

General usage — Managing strata

Which **stratum** is providing the running process 3944?

- ▶ `$ bri -p 3944`
 - ▶ `3944 xterm (wheezy)` → **Wheezy** is providing process with pid 3944, which is `xterm`.
- ▶ Can also give executable name (will use `pidof` behind-the-scenes).
- ▶ `$ bri -p xterm`
 - ▶ `1679 xterm (wheezy)`
 - ▶ `3944 xterm (wheezy)`
 - ▶ `4810 xterm (wheezy)`

General usage — Managing strata

What processes are provided by the Arch stratum?

- ▶ `$ bri -P arch`
 - ▶ 2237 `dbus-launch (arch)`
 - ▶ 2239 `dbus-daemon (arch)`
 - ▶ 2900 `firefox (arch)`

General usage — Managing strata

Lots of other things available, see `$ bri -h`

General usage — Managing strata

Run command in/from all **strata**: use **brl**

- ▶ e.g.: `$ brl brl-implied explicit sha1sum direct access /path/to/file`
 - ▶ Check for file duplication across **strata**
- ▶ e.g.: `# brl -c "bri -w apt-get|grep \"(direct)\\$\\\" apt-get update`
 - ▶ Has every available version of **apt-get** run with **update** option.
- ▶ e.g.:
`# bri -c "[-e /var/lib/dpkg/statoverride]" sh -c "echo -n \\\"\\\" > /var/lib/dpkg/statoverride"`
 - ▶ Empties the contents of **/var/lib/dpkg/statoverride** associated with every **stratum** that has one.

Planned for Nyla

Planned for Nyla — init

- ▶ Get init from any distro
 - ▶ `openrc`
 - ▶ `systemd`
 - ▶ `upstart`
 - ▶ `bsd-style`
 - ▶ `runit`
 - ▶ `s6-init`
 - ▶ `cinit`
 - ▶ `etc`
- ▶ Functional proof-of-concept done.

Planned for Nyla — Hijack install

- ▶ Convert a pre-existing traditional distro install into **Bedrock Linux**
- ▶ Will turn original install into a **stratum**
- ▶ Will *probably* support reverting to original install.
- ▶ Or drop original install's files and continue with **Bedrock Linux**
 - ▶ not installed “onto” pre-existing install

Planned for future

Planned for future — tab-completion

- ▶ **Bedrock Linux** comes with numerous (≈ 8) utilities which currently do not have tab completion support.
- ▶ We're working on tab completion for **bash** and **zsh**.
 - ▶ Should be quite possible to add support for other shells (e.g.: **fish**) if there is interest.

Planned for future — brg

brg: “BedRock linux Get **stratum**”

- ▶ Acquiring files for a **stratum** a bit of work.
- ▶ **brg** will automate the process.
- ▶ Ideally, one command to acquire **stratum**, setup, and enable **stratum**. Next command can then be command from **stratum**.

Planned for future — pmm

`pmm`: “package manager manager”

- ▶ Will abstract away differences between package managers.
- ▶ Examples:
 - ▶ `$ pmm install arch firefox`
 - ▶ Install `firefox` from `Arch stratum`.
 - ▶ `$ pmm install any sage-mathematics`
 - ▶ Install `sage-mathematics` from first `stratum` found which provides `sage-mathematics`.
 - ▶ `$ pmm install newest libreoffice`
 - ▶ Install `libreoffice` from `stratum` which provides newest version of `libreoffice`.
